Tabulation of the Blasius Function with Blowing and Suction.

- By -
 H. W. Emmons and D. C. Leigh.

Communicated by Prof. W. A. Mair.

5th June, 1953

The Blasius differential equation $f''' + ff'' = 0$ for the velocity distribution in a boundary layer is too well known to warrant any derivation here. Most books on theoretical aerodynamics contain a derivation. In particular the reader is referred to "Modern Developments in Fluid Mechanics"¹, Vol. 1., p. 116, or "Aerodynamic Theory"², Vol. III, p. 80.

The velocity components, u , along and, v , perpendicular to the surface are given in terms of f far away from the boundary layer by

$$\frac{u}{u_\infty} = \frac{1}{2} \frac{df}{d\eta} = \frac{1}{2} f' \quad \dots(1)$$

$$\frac{v}{u_\infty} = \frac{1}{2} (\eta f' - f) \frac{1}{Re^2} \quad \dots(2)$$

where u_∞ is the undisturbed velocity outside of the boundary layer, and

$$Re = \frac{u_\infty x}{v}$$

The co-ordinate η is related to the position, x , along end, y , perpendicular to the plate by the equation

$$\eta = \frac{1}{2} \left(\frac{u_\infty}{v} \right)^{\frac{1}{2}} \frac{y}{x^{\frac{1}{2}}} \quad \dots(3)$$

in the case of an incompressible fluid.

The case of a compressible fluid boundary layer can often be solved by the same Blasius equation by making the relatively mild assumption

$$\rho \mu = \text{constant.} \quad \dots(4)$$

The /

The corresponding velocity components and co-ordinate are

$$\frac{u}{u_\infty} = \frac{\frac{1}{2}f'}{u_\infty} \quad \dots(5)$$

$$\frac{\rho v}{\rho_\infty v_\infty} = \frac{1}{2}(\eta f' - f) \frac{1}{Re^2} - \frac{f'}{2} \int_0^y \frac{\partial}{\partial x} \left(\frac{\rho}{\rho_\infty} \right) dy \quad \dots(6)$$

$$\eta = \frac{1}{2} \left(\frac{u_\infty}{v} \right)^{\frac{1}{2}} \frac{1}{x^{\frac{1}{2}}} \int_0^y \left(\frac{\rho}{\rho_\infty} \right) dy, \quad \dots(7)$$

This can be considered to be the reduction of the compressible fluid boundary layer to the corresponding incompressible boundary layer if desired, but little is gained by so doing.

A long distance from the plate the velocity component along the plate becomes equal to the free stream velocity $u(\infty) = u_\infty$. Thus the boundary condition at $\eta = \infty$ is

$$\frac{u(\infty)}{u_\infty} = \frac{1}{2}f'(\infty) = 1 \text{ at } \eta = \infty. \quad \dots(8)$$

For a stationary plate, $u = 0$ at the plate and a second boundary condition is

$$f'(0) = 0 \quad \text{at } \eta = 0. \quad \dots(9)$$

The only cases of moving plate ($u(0) \neq 0$), reducible to the Blasius equation involve a plate velocity proportional to $x^{-\frac{1}{2}}$ for which there are no practical applications known to the authors. Most such cases, should they arise, could be solved by use of a fictitious origin for η . $f''(0) = 0$ at $\eta = 0$ is used throughout these tables.

For a non-porous plate the third boundary condition is $v(0) = 0$ at $\eta = 0$ or

$$f(0) = 0 \quad \text{at } \eta = 0. \quad \dots(10)$$

In the case of a porous wall through which fluid is being blow or sucked, the normal velocity component v is not zero. Only in the case of $v(0,x)$ proportional to $x^{-\frac{1}{2}}$, as required by equations (2) or (6), is the boundary layer problem reducible to that of Blasius equation. Such inverse half paver blowing or suction distribution is only conveniently attained if the normal surface velocity is controlled by the boundary layer itself through its mass and heat transfer properties.

It was in connection with the solution of a combustion problem that the present solutions were obtained.

The normal velocity at the plate can conceivably take any value between $-\infty$ and $+\infty$ by attaching the proper blowing or suction device to the plate. However, Lock's solution of a laminar jet mixing problem can be interpreted as showing that at a certain blowing velocity (corresponding to $f(0) = -1.23849\dots$) the boundary layer is "blown away". Mathematically $f(0)$ must be $-1.23849\dots$ if $f''(0) = 0$ and $f'(\infty) = 2$. In this case the differential equation gives $f'(\eta) = 0$ for all finite η .

Physically/

Physically there are two aspects to this limit case. As noted above, a high blowing velocity may supply fresh gas (with zero velocity along the plate) at such a high rate that the available viscous mechanism is not strong enough to accelerate it. Hence, a steady boundary layer is impossible & it is blown away. When dealing with a flat plate as above, the large blowing velocity causes the boundary layer to become thick, which makes the boundary layer approximation3 incorrect and hence the Blasius equation is no longer an adequate description. Look considered the laminar boundary layer between two two-dimensional jets with (in general) different properties. If the two jets are identical except that one has velocity $u = 0$ while the other has velocity $u = u_\infty$, then the boundary layer between them has the properties of the limit case. The streamline $f = 0$ is the dividing line for the fluid from the two jets. The present solutions cover the whole possible range of blowing and suction values.

The third boundary condition used in these Tables is therefore a specification of a set of specific values of $f(0)$. The values selected are:-

$$f(0) = -1.23849, -1.20, (0.05) 0.50 (0.1) 1.5, 2, 2.5, 3, 4, 5, 6, 10, \dots (n)$$

The important aerodynamic mass flow coefficients are

$$\text{Local friction coefficient} = \frac{\tau}{\frac{1}{2}\rho_0 u_\infty^2} = \frac{f''(0)}{2Re^{\frac{1}{2}}} \dots (12)$$

$$\text{Local mass flow coefficient} = \frac{\rho_0 v_0}{\rho_0 u_\infty} = -\frac{f(0)}{2Re^{\frac{1}{2}}} \dots (13)$$

$$\text{Mean friction coefficient} = \frac{\text{Drag}}{\frac{1}{2}\rho_0 u_\infty^2} = \frac{f''(0)}{Re_L^{\frac{1}{2}}} \dots (14)$$

$$\text{Mean mass flow coefficient} = \frac{\text{Injected Mass}}{4\rho_0 u_\infty} = -\frac{f(0)}{Re_L} \dots (15)$$

$$\text{Ratio} \frac{\text{mass flow}}{\text{sheer stress}} = -\frac{f(0)}{f''(0)}. \dots (16)$$

Figures 1, 2 and 3 show a sample set of f , f' and f'' curves, while the tables give the values to six figures for η , f , f' , f'' , f''' for each of the $f(0)$ values given by equation (11). The limit case $f(0) = -1.23849$ was recomputed in the present work and differs from Lock's values by 1 in the 4th decimal. Note that in this Case the co-ordinate is ξ and is measured point where $f = 0$ in the boundary region and extends to infinity both ways.

Previous calculations (for cases $f(0) = -1, -0.75, -0.5, 0, 0.5, 1, 1.5, 5$) were given to four decimal places by H. Schlichting and K. Bussmann⁴. These hand computed tables generally agree to better than 5 in the last place with the present ones.

The boundary values of $f(0)$, $f''(0)$ and their ratio are given in Table I.

The calculations were done on the **EDSAC** (Electronic Delay Storage Automatic Calculator). A programme of operations for the EDSAC was drawn up for the integration of the differential equation $f''' + ff'' = 0$ using the standard sub-routine designed, by **Gill5**, for the step-by-step integration of a set of simultaneous ordinary differential equations. This method has been used extensively on automatic calculating machines because it is flexible, does not require a special procedure for the first few steps, and uses comparatively little storage space of the machine. In order to satisfy two-point boundary conditions, one must integrate over the entire range several times until the values for the unknown initial conditions are obtained which give a solution satisfying the conditions at the far end of the range. For this equation, for an accuracy of six figures, "infinity" occurs on the average at about the value 5 of the independent variable.

In order to speed up the process of iteration, it was suggested by Professor D. R. Hartree that the equation

$$f''' + ff'' = 0 \quad \dots(17)$$

be differentiated with respect to $f''(0) = f'_0$, giving

$$\left[\frac{\partial f}{\partial f''} \right]''' + f \left[\frac{\partial f}{\partial f''} \right]'' + f'' \left[\frac{\partial f}{\partial f''} \right]' = 0 \quad \dots(18)$$

and that (17) and (18) be solved simultaneously. All the boundary conditions of equation (18) are known at the beginning, i.e.,

$$\left[\frac{\partial f}{\partial f''} \right]_0 = 0, \quad \left[\frac{\partial f}{\partial f''} \right]'_0 = \text{no} \left[\frac{\partial f}{\partial f''} \right]_0 f = 1. \quad \dots(19)$$

From the solution of (18) we get the variation of $f''(\omega)$ with $f''(0)$ and hence a very good estimate of the next trial $f''(0)$ can be obtained. In order that this process should have any advantage over the solution of $f''' + ff'' = 0$ accompanied by an iteration process such as the Newton-Raphson method, it should converge in half as many integrations over the range, since the integration process for the two equations will be approximately twice as slow as for one. Experience has shown that this is usually the case, although it was not actually checked in this instance, since the machine time of the problem was fairly short in any event.

Two programmes were constructed. The first programme was for the determination of the unknown initial condition $f''(0)$. Six figure accuracy in the solution was obtained by making the interval in the independent variable 0.1 in most cases. Because the range of integration becomes increasingly contracted for the higher values of $f(0)$, the interval $f(0) > 2.5$ was made 0.05 to get the same accuracy. Estimates of $f''(0)$ obtained by interpolation of the Schlichting and Bussmann⁴ values were accurate to about two and a half figures and it took about three or four runs over the range in order that successive values of $f''(0)$ were the same to at least six figures. The process took about five minutes for each value of $f(0)$. The second programme was for a final integration with the tabulation of f , f' , f'' , f''' and η at intervals of 0.1 or 0.05, as the case may be. This took about 10 minutes for each value of $f(0)$.

The limiting value $f(0) = -1.23849$ was found by setting $f''(0) = 0,000,000,1$ and altering slightly the first programme mentioned above so that $f(0)$ was adjusted with each integration over the η range and $f''(0)$ remained fixed. The origin was then shifted to $f = 0$ by interpolation.

The equation $f''' + ff'' = 0$ has a property which might be used to avoid a number of successive integrations over the complete range. By a change of dependent and independent variables from f and η to F and ξ by means of the relations $aF(\xi) = f(n)$ and $\xi = an$, we have that F satisfies the same equation as f . From values of $f(0)$, $f'(0)$ and $f''(\infty)$, one can determine a value of a such that $F'(\infty) = 2$. The corresponding values of $F(0)$ and $F''(0)$ would be given by

$$F(0) = \left(\frac{2}{f''(\infty)} \right)^{\frac{1}{2}} f(0) \quad \text{and} \quad F''(0) = \left(\frac{2}{f''(\infty)} \right)^{\frac{3}{2}} f''(0),$$

If the values of $f(0)$ were at equal intervals, the corresponding values of $F(C)$ would be slightly off the equal intervals, and it would have been necessary to interpolate in order to have $F(0)$ at equal intervals. This added complication would likely not have resulted in a saving of very much machine time and would have meant additional programming.

We acknowledge our indebtedness to Dr. M. V. Wilkes for the use of the facilities of the Cambridge University Mathematical Laboratory for the solution of this problem.

The Tables

Table I, page 7

The initial values of $f(0)$, $f''(0)$ and $f(0)/f''(0)$ for all cases solved. The complete tabulated solution for each of these cases is given in Tables II and III.

Table II, pages 8-10

The limit case $f(0) = -1.23849\dots$ Values of f , f' , f'' , f''' are given for positive (page 8) and negative (pages 9, 10) values of ξ beginning with $\xi = 0$, at $f = 0$.

Table III, pages II-78

Values of f , f' , f'' , f''' are given for the values of $f(0)$ given at the top of each page.
